2. Consider a method of encoding and decoding words that is based on a *master string*. This master string will contain all the letters of the alphabet, some possibly more than once. An example of a master string is "sixtyzipperswerequicklypickedfromthewovenjutebag". This string and its indexes are shown below.

| | | 1 | | | | | | | | | | | | | | | | | | | | | | |
|---|---|----|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | S | i | х | t | У | Z | i | р | р | е | r | s | W | е | r | е | q | u | i | С | k | 1 | У | р |
| | | | | | | | | | | | | | | | | | | | | | | | | |
| | | 25 | | | | | | | | | | | | | | | | | | | | | | |
| 8 | i | С | k | е | d | f | r | 0 | m | t | h | е | W | 0 | V | е | n | j | u | t | е | b | a | g |

An encoded string is defined by a list of *string parts*. A string part is defined by its starting index in the master string and its length. For example, the string "overeager" is encoded as the list of string parts [(37, 3), (14, 2), (46, 2), (9, 2)] denoting the substrings "ove", "re", "ag", and "er".

String parts will be represented by the StringPart class shown below.

The class StringCoder provides methods to encode and decode words using a given master string. When encoding, there may be multiple matching string parts of the master string. The helper method findPart is provided to choose a string part within the master string that matches the beginning of a given string.

```
public class StringCoder
  private String masterString;
  /** @param master the master string for the StringCoder
                Precondition: the master string contains all the letters of the alphabet
    * /
  public StringCoder(String master)
  { masterString = master;
   /** @param parts an ArrayList of string parts that are valid in the master string
                Precondition: parts.size() > 0
      @return the string obtained by concatenating the parts of the master string
  public String decodeString(ArrayList<StringPart> parts)
      /* to be implemented in part (a) */
   /** @param str the string to encode using the master string
                Precondition: all of the characters in str appear in the master string;
                             str.length() > 0
       @return a string part in the master string that matches the beginning of str.
                  The returned string part has length at least 1.
    * /
  private StringPart findPart(String str)
      /* implementation not shown */ }
   /** @param word the string to be encoded
                Precondition: all of the characters in word appear in the master string;
                             word.length() > 0
       @return an ArrayList of string parts of the master string that can be combined
                 to create word
    * /
  public ArrayList<StringPart> encodeString(String word)
      /* to be implemented in part (b) */
  // There may be instance variables, constructors, and methods that are not shown.
```

}

(a) Write the StringCoder method decodeString. This method retrieves the substrings in the master string represented by each of the StringPart objects in parts, concatenates them in the order in which they appear in parts, and returns the result.

Complete method decodeString below.

```
/** @param parts an ArrayList of string parts that are valid in the master string  
* Precondition: parts.size() > 0  
* @return the string obtained by concatenating the parts of the master string  
*/ public String decodeString(ArrayList<StringPart> parts)
```

(b) Write the StringCoder method encodeString. A string is encoded by determining the substrings in the master string that can be combined to generate the given string. The encoding starts with a string part that matches the beginning of the word, followed by a string part that matches the beginning of the rest of the word, and so on. The string parts are returned in an array list in the order in which they appear in word.

The helper method findPart must be used to choose matching string parts in the master string. Complete method encodeString below.

```
/** @param word the string to be encoded

* Precondition: all of the characters in word appear in the master string;

* word.length() > 0

* @return an ArrayList of string parts of the master string that can be combined

* to create word

*/
public ArrayList<StringPart> encodeString(String word)
```
